INTRODUCTION

- Cutaneous lupus erythematosus (CLE) is the cutaneous form of a common autoimmune disease, lupus erythematosus, driven by a dysfunction within the adaptive and innate immune system.1
- Chronic CLE (CCLE), one of the 3 subcategories of CLE per histopathology and clinical findings. The most common clinical subtype of CCLE is Discoid Lupus Erythematosus (DLE) in which lesions are often hypopigmented and atrophic and can lead to scarring.1,2
- Treatment typically includes preventative approaches, topicals (corticosteroids or calcineurin inhibitors), and systemic therapies.1
- Here we report a case of a patient with systemic and refractory cutaneous disease with improvement in manifestations demonstrating efficacy following treatment with roflumilast cream 0.3% in a complex chronic CLE patient with uncontrolled disease, intense pruritus and scarring.

CASE PRESENTATION

- A 48-year-old Asian female with history of smoking, chronic refractory SLE since 2008 with a new onset of pruritic rash.
- Previous therapies including thalidomide, hydroxychloroquine, methotrexate, mycophenolate mofetil, numerous research trials, oral and intramuscular steroids that failed to control her systemic LE.

TABLE 1. Office Visit Timeline

<table>
<thead>
<tr>
<th>Date</th>
<th>Office Visit Notes</th>
<th>Treatment(s) Prescribed</th>
</tr>
</thead>
<tbody>
<tr>
<td>October 2021</td>
<td>A Rheumatology colleague referred the patient for new onset cutaneous manifestations. Initial presentation revealed lesions involving 2% of the occipital scalp. Pathology confirmed the diagnosis of discoid lupus.</td>
<td>Intrallesional triamcinolone, plus topical betamethasone dipropionate 0.05% twice daily (BID) and timolol 0.5% OP solution for wound healing were initiated.</td>
</tr>
<tr>
<td>January 2023</td>
<td>Fifteen months later the patient had disease progression of her CLE on to her scalp, face, legs and arms, with the chief complaint of persistent pruritus despite oral prednisone, hydroxychloroquine and thalidomide. The patient’s rheumatologist requested alternative treatment for cutaneous disease without use of long term topical high potency steroids (Figure 1A and 1B).</td>
<td>A second series of intrallesional triamcinolone injections plus betamethasone dipropionate 0.05% BID for 3-4 weeks and titrate down to 2-3 applications per week Roflumilast cream 0.3% was initiated once daily to her face, scalp, and lower legs.</td>
</tr>
<tr>
<td>March 2023</td>
<td>On the third office visit, four weeks later, the patient reported pruritus and cutaneous manifestations in lower legs controlled and scalp and face have marked improvement</td>
<td>No change in treatments</td>
</tr>
<tr>
<td>April 2023</td>
<td>After 8 weeks on this regimen, the patient return reported that scalp and face continued to improve and disease on the legs continue to be controlled despite not using topical treatment for four weeks.</td>
<td>Roflumilast cream 0.3% once daily was continued as monotherapy</td>
</tr>
<tr>
<td>June 2023</td>
<td>Two months later, the patient reported that her skin was fully controlled was starting to repigment with monotherapy (Figure 1C and 1D).</td>
<td></td>
</tr>

CONCLUSIONS:

- This case report of a 48-year-old female with refractory treatment resistant chronic SLE and CLE treated with roflumilast cream 0.3%, a phosphodiesterase-4 (PDE-4) inhibitor, resulted in disease control, the symptom improvement of improved pruritus as well as repigmentation of the skin.
- The results observed in this patient suggest this topical intervention, if implemented at the beginning of treatment for cutaneous onset of disease, may have the potential to halt the progression of cutaneous involvement.
- This case report serves to highlight a promising intervention that may lead to better cutaneous control without long term side effects of topical steroid use.
